Vine Copulas

Exercise 18-5: Vine Copula

Problem Statement & Introduction

“Pure” factor portfolios (long/short, dollar-neutral baskets that isolate one characteristic such as Value or Momentum) are built to be mutually uncorrelated in sample, yet their realized returns still show:

- Non-linear spill-overs (e.g., the combined Value + Quality crash of 2020),
- Asymmetric tail dependence (Momentum often rallies in mild sell-offs until a sharp reversal wipes out both Momentum and Low-Volatility), and
- Regime-switching cross-correlations (factors decouple in calm times but cluster in crises).

Classical multivariate-normal or linear-beta frameworks cannot capture these subtleties, whereas vine copulas⁸⁸ (hierarchical assemblies of bivariate copulas) model any mix of lower-tail, upper-tail and symmetric dependence, yielding materially better VaR and ES forecasts for factor portfolios.

Key Advantages of Vine Copulas for Pure-Factor Models

- Tail Dependence: Many financial factors exhibit stronger co-movement in extreme markets.
- Asymmetry: You can select Clayton to capture lower-tail clustering, Gumbel for upper tails, or Student's t for symmetric fat tails.
- Dimension Scalability: Instead of fitting one large 10×10 multivariate copula outright, you fit a sequence of bivariate copulas.
- Interpretability: You see which pairs of pure factors have significant tail coupling.
